- 4. A 3D object, O, can be viewed from a position  $\mathbf{p}$  by looking in direction  $\mathbf{v}$ .
- (a) Sketch the viewing geometry giving all parameters required to map the object on to a view plane. [5]
  - object on to a view plane. [5]

    (b) If a viewport on the view plane has size  $W \times H$ , what 3D and 2D transformations are required to project vertices of O ensuring that those inside the viewport are in the range [0,1]? [6]
  - formations are required to project vertices of O ensuring that those inside the viewport are in the range [0,1]? [6]

    (c) How can the edges of the object be efficiently clipped to the viewport using the Sutherland-Cohen method? Illustrate your answer with three typical cases
  - (c) How can the edges of the object be efficiently clipped to the viewport using the Sutherland-Cohen method? Illustrate your answer with three typical cases. [7]
    (d) Write down the set of inequalities for the line (x₁, y₁) → (x₂, y₂) which are necessary to set up the Liang-Barsky clipping algorithm on a normalised viewport. State the parameter values for intersections of the line with the four edges of the viewport. [7]
